

IN THE ABSTRACT:

Please add an abstract as follows:

An inkjet printer has a print head unit with four parallel rows of nozzles each row being able to receive an ink of a different color. The length of each row is less than the length of the print head unit. A number of print head units may be aligned together to provide elongate arrays of nozzles. The nozzle spacing along the array is non-uniform in that the inter-nozzle spacing within the rows is less than the inter-row spacing between neighboring print head units. In operation each print head unit deposits a non-contiguous swath on the paper and then all the units are moved an equal distance and a further swath printed thereby interleaving the swaths. A method of supplying ink and an ink supply member are also provided.
